

Case Study

Pure Gases Monitoring Applications

Dissolved gases analysis in water

Context & Challenges

Some companies are using water cooler systems where oxygen concentration needs to be controlled in continuous: to avoid corrosion problems. Less oxygen in water involve less corrosion problems in the pipes. A detection limit of 5 ppb of oxygen in water is required.

Chromatotec® Solutions

Chromatotec® has developed a specific system for the measurement of oxygen, nitrogen and hydrogen in water. The analyzer is coupled with a degassing system allowing the extraction of dissolved gases.

Degassing system

A continuous degassing system using an inert gas was used to extract oxygen, nitrogen and hydrogen from water. A constant controlled flow of water is passing through a small pipe and is sucking an inert gas. Then, the extracted gases will go to the analyzer to be analyzed. The amount of inert gas is precisely controlled by a Mass Flow Controller (MFC).

A calibration system with a Faraday cell is used to validate the results. This cell is producing a known quantity of oxygen and hydrogen allowing calibration of the instrument.

The different parts of the degassing system are:

- Online water input (accurate flow control)
- A complete glassware especially designed for dissolved gas extraction
- Inert gas inlet precisely controlled with Mass Flow Controller
- Faraday cell piloted by Vistachrom for online calibration
- Sample output through Vigreux column directed to the analyzer
- Water event

The system is designed to extract most of the components dissolved in water: permanent gases and/or VOCs.

Analyzer: chromaTCD

The fully automatic analyzer dedicated to this application is our new high performance chroma using special μ TCD detector. The Limit of Quantification (LOQ) for this system is around 3 ppb of dissolved oxygen in water. The analyzer needs high purity helium cylinder (6.0) as carrier gas coupled to a gas purifier.

This analyzer is used to continuously monitor dissolved gases (oxygen, hydrogen, nitrogen) in water.

Technical information and results

Calibration

To be able to ensure good quality of results, Chromatotec® has used an online Faraday cell to produce a known quantity of oxygen and hydrogen based on water electrolysis. Therefore, if the water flow and the applied current are stable and well known parameters, it is possible to have an accurate control of oxygen concentration produced. Then, a comparison of experimental and theoretical values is made to validate the whole system.

Here in the opposite column is an example of calibration made with the Faraday cell. In this example, the peak area variations before and after the use of the calibration device (calculated with the following formula) are used to calibrate the system.

$$C = (K \times I) / Q$$

With K: known constant (depending on Faraday cell)
 C: produced oxygen concentration in $\mu\text{g.kg}^{-1}$
 I: current applied through Faraday cell in mA
 Q: water flow passing through the degassing system in mL.mn^{-1} .

To study the linearity and the behavior of the whole system, several calibration points were made at different oxygen concentrations (different Faraday cell intensities). The first point corresponds to the dissolved oxygen concentration in standard conditions. The different results were obtained at fixed water flow and temperature conditions. Several analyses were made for each conditions and the average with the error bars are plot in Fig. 2.

Figure 3 is an oxygen concentration trend for more than 5 hours of measurement and two calibrations made with the same conditions.

We have studied the retention time stability over 45 hours for oxygen and nitrogen.
 The relative standard deviation on retention time over the selected period is below 0.5%. Some results are displayed in Fig. 4.

Conclusion:

Chromatotec® has developed a specific system for the measurement of dissolved gases in water. The key point of this system is the on-line validation of results by production and analysis of standard (oxygen and/or hydrogen). Then, Chromatotec® bring its expertise with the new high performance chromaTCD using μTCD detector for higher sensitivity.

This new instrument allows the measurement of dissolved oxygen at concentration as low as 5 ppb.
